*“Obtaining and maintaining quality data is challenging and remains a critical task for all of our countries”*

**Carissa F. Etienne**

## PREFACE

For the 23rd consecutive year the publication, *Health Situation in the Americas: Core Indicators* has provided the latest information on key health indicators for the Region of the Americas.

This edition includes 82 core indicators for the countries, territories, and subregions of the Americas, which are categorized as follows: demographic-socioeconomic, health status, risk factors, services coverage, and health systems. Information is also included on 17 of the 27 indicators of Goal Three of the Sustainable Development Goals (SDGs), which is to *Ensure healthy lives and promote well-being for all at all ages*. We encourage you to visit PAHO's online Platform for Health Information at [www.paho.org/plisa](http://www.paho.org/plisa) for the complete data set of core indicators.

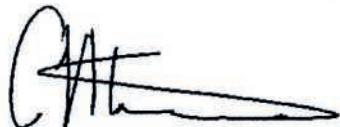

Obtaining and maintaining quality data is challenging and remains a critical task for all of our countries. Additionally, the extensive scope of the 2030 Agenda for Sustainable Development will require even greater efforts and focus for monitoring its indicators. Nevertheless, having seen the commitment of our countries and the gradual and continuous improvements in the quality of the data that we collect, I am optimistic that our Region is on the right track. The Pan American Sanitary Bureau remains committed to strengthening country capacity to ensure the generation of reliable, valid data in real time.

This year's publication presents an analysis of the following topics:

- The obstetric transition and the distribution of causes of maternal deaths, highlighting the increase in indirect obstetric causes and late maternal deaths and sequelae at the regional level. It is imperative to implement interventions that aim to reduce maternal deaths and improve the overall health of women.
- The status of progress towards meeting the impact goals of the 2014–2019 PAHO Strategic Plan two years prior to its conclusion. This analysis presents the trends for the regional targets of six health indicators: healthy life expectancy, infant mortality ratio, maternal mortality ratio, mortality amenable to health care, the rate of premature mortality from noncommunicable diseases, and the HIV/AIDS mortality rate.
- The health inequalities measured through adolescent fertility, as this indicator is considered useful for identifying inequalities between populations.

The data presented in this publication were collected by the countries and validated by the technical entities of the Bureau. This publication would not have been possible without the collaboration between the Ministries of Health and the national statistical institutes of the countries and territories of the Americas, as well as the various specialized agencies of the United Nations system. For this, I am very grateful.

I hope this publication continues to be an invaluable source of data on the health of the people of the Americas.

Dr. Carissa F. Etienne, Director

Health Systems  
Analysis

Between 1990 and 2015, maternal mortality declined by 44% worldwide and by 50% in the Americas. In spite of this progress, 22 women die in the Region every day due to preventable causes related to pregnancy, childbirth, and the puerperium. Adolescents and women above the age of 34 are at an increased risk of complications and death as a consequence of pregnancy (1).

## BOX

- Maternal deaths can be divided into two groups:

**Direct obstetric causes:** those resulting from obstetric complications of the pregnant state (pregnancy, labor, and puerperium), from interventions, omissions or incorrect treatment, or from a chain of events resulting from any above (2).

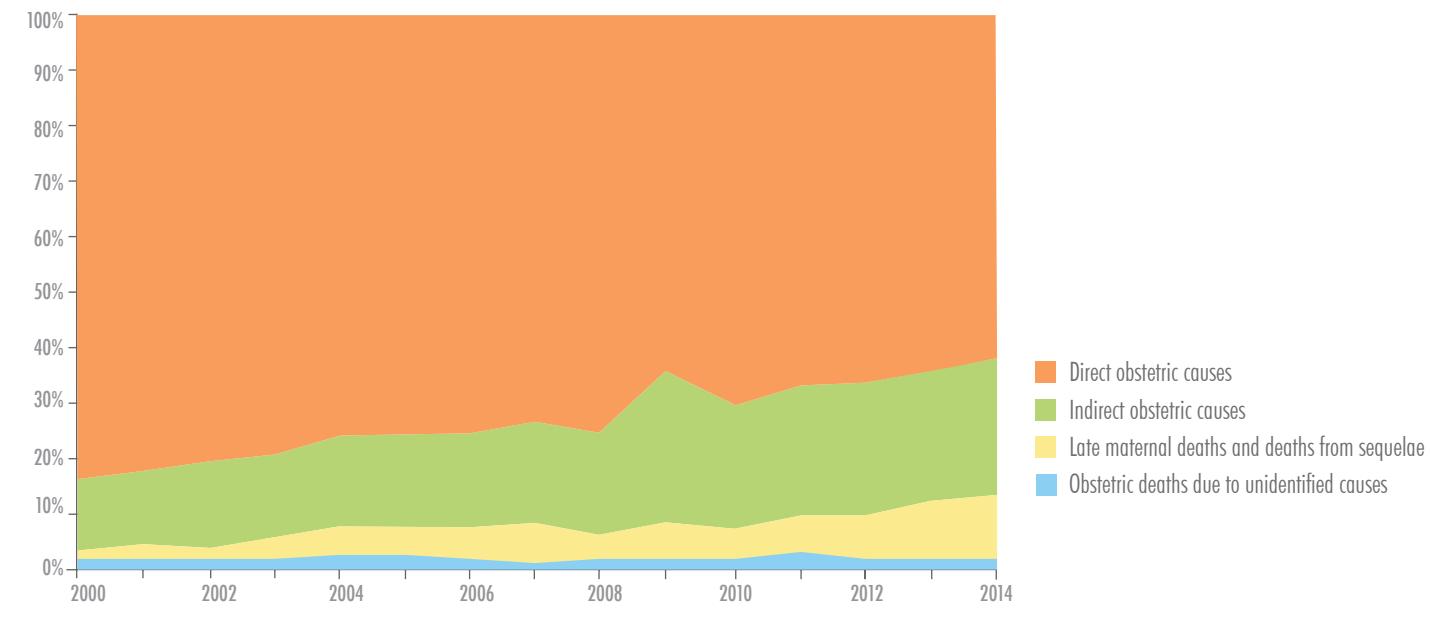

**Indirect obstetric causes:** those resulting from previous existing disease or disease that developed during pregnancy and that was not due to direct obstetric causes, but that was aggravated by physiologic effects of pregnancy (2).

Additional categories are **late maternal deaths and deaths from sequelae of direct or indirect obstetric causes** occurring more than 42 days but less than one year after termination of pregnancy, and deaths occurring a year or more after the termination of pregnancy respectively (2).

In the Region of the Americas, the burden of **direct obstetric causes** was 62% in 2014, with eclampsia and obstetric hemorrhage accounting for 45% of this number. The burden of **indirect obstetric causes**, which complicate pregnancy, childbirth, and the puerperium, was 25%, among which circulatory system diseases were especially significant (28%), followed by respiratory system diseases (15%), and digestive system diseases (7%). Tuberculosis, an example of an infectious indirect obstetric cause, was responsible for 2% of maternal deaths in 2014. Another example of an indirect obstetric cause is pandemic influenza A (H1N1), which, in 2009, was responsible for the increase in maternal deaths in several of the Region's countries. The figure below shows the spike caused by this event. The burden of **late maternal deaths and deaths from sequelae** was 12% in 2014.

## FIGURE

- Proportional distribution of causes of maternal death in the Americas, 2000-2014

Source: PAHO/WHO Regional Mortality Database.

This mortality pattern varies based on the country and on whether the country makes specific attempts to identify maternal deaths, a process that highlights the importance of the **obstetric transition** (3) and the challenge that the Region faces in reducing not only direct obstetric deaths but also indirect ones and those that occur after puerperium. The obstetric transition consists of changing from a pattern of high maternal mortality to one of low maternal mortality, with indirect obstetric causes assuming a greater burden as direct obstetric causes recede in relative importance. This change is a function of the increasing age of mothers during their first pregnancy, along with an increase in noncommunicable chronic diseases in the mother, institutionalization of pregnancy and childbirth care, and an increase in obstetric interventions. The transition has five stages, which are classified principally according to the magnitude of the maternal mortality ratio (MMR), the pattern of mortality causes, and fertility levels (see Table). Considering the regional MMR value of 46.8 per 100,000 live births (1b) (4), the current stage is stage IV, with a moderately low MMR and an upward trend in indirect obstetric causes associated primarily with noncommunicable diseases. Countries are undergoing the transition at varying paces. Three stages can be seen in the Region: countries in stage II have MMRs in the 990-300 range, countries in stage III have MMRs in the 299-50 range, and countries in stage IV have MMRs of less than 50.

TABLE

► Obstetric transition

Stage	Maternal mortality ratio (100,000 lb)	Characteristic
I	> 1,000	Very high maternal mortality, high fertility, and the predominance of direct obstetric causes, alongside a significant proportion of deaths attributable to communicable causes. Serious limitations on access to health facilities.
II	999 - 300	High maternal mortality and high fertility, with mortality patterns similar to stage I, but with a higher proportion of women seeking and having access to health facilities.
III	299 - 50	High maternal mortality, variable fertility, and direct causes of mortality still predominate but with a higher proportion of women having access to health services. Births attended by qualified personnel and services with primary, secondary, and tertiary prevention.
IV	49 - 5	Maternal mortality moderate to low, low fertility, and indirect obstetric causes, particularly non-communicable diseases, acquire greater importance. Access to high-quality health services with adequately trained personnel and material resources for the detection and care of emergencies with better health outcomes.
V	< 5	Very low maternal mortality, very low fertility, with a predominance of indirect obstetric causes. Avoidable maternal deaths are effectively and practically avoided in health services.

Source: Prepared from Souza J, Tunçalp Ö, Vogel J, Bohren M, Widmer M, Oladapo O, et al. Obstetric transition: the pathway towards ending preventable maternal deaths. *BJOG An Int J Obstet Gynaecol.* 2014;121:1–4. Available at: <http://doi.wiley.com/10.1111/1471-0528.12735>

All of the countries in the Americas are taking action to reduce maternal deaths and this has generated valuable experiences. However, efforts are needed to drastically improve high-quality prenatal care, availability of specialized care for complications during delivery, monitoring during the first weeks following delivery, and good access to family planning.

Several countries are simultaneously developing strategies to improve the quality of maternal death information, measurement, and classification, while also conducting an active search to identify these deaths in order to not only establish the number of deaths but also to know each woman's history. This information provides essential input for detecting relevant factors and for preventing further deaths. Attention also needs to be given to late maternal deaths and deaths from sequelae in order to determine the magnitude and behavior of this phenomenon, as improvements in care are resulting in a shift of deaths to the post-puerperium period (5).

It is also necessary to verify that each country has adopted the 1990 World Health Assembly recommendation that death certificates should include questions to determine if the deaths of women of reproductive age occurred during pregnancy, childbirth, or puerperium, or whether the woman had been pregnant within the one-year period preceding death. This information is very useful for the coder who selects the underlying cause of death, as well as for the active search of maternal deaths. In addition to the adoption of this recommendation, it is necessary to strengthen the quality of the filling out of death certificates by the responsible personnel.

The increase in indirect obstetric causes must be given proper attention with focused efforts on reducing them (6). The rise in indirect causes could be the result of successfully dealing with the direct complications of pregnancy and childbirth and a change in risk factors and disease patterns. Analyzing deaths due to indirect causes at the national and subnational levels is essential so that necessary and immediate action can be taken to bolster regional progress in reducing maternal mortality.

In the framework of the Pan American Health Organization Strategic Plan 2014-2019 (SP 2014-2019) (1), the Organization's Member States approved the monitoring of nine goals and their indicators, in order to evaluate, by late 2019, the impact of the countries' public health actions, and thereby contribute to improving health in the Region.

The present analysis describes trends, with respect to regional targets, for six health indicators: healthy life expectancy at birth, infant mortality rate, maternal mortality ratio, mortality due to poor quality health care, premature deaths due to noncommunicable diseases, and HIV/AIDS mortality rates.

Information used for indicators on mortality due to poor quality health care, premature deaths due to noncommunicable diseases, and HIV/AIDS mortality rates is drawn from PAHO/WHO Member Country data for 1999-2012 (14 years). Data on healthy life expectancy at birth were generated by the Institute for Health Metrics and Evaluation (2), while information on the infant mortality rate and maternal mortality ratio is derived from WHO data produced by the interagency groups charged with estimating maternal (3) and child mortality (4).

Using the indicators to make projections for 2014 and 2019, an exponential regression model was employed, based on the nature of the temporal data series. The model estimated percentage increases/reductions, along with their 95% confidence intervals (CI). It is worth noting that the 2014 projections do not necessarily coincide with the baseline SP 2014-2019 values. The slight differences are due to changes in the regional database as countries provide updated data. Thus, the available country/year mortality data vary over time, affecting the indicators' values. For example, the 2014 infant mortality rate projection—made when the SP 2014-2019 indicators for the goals were calculated, and based on data current at that time—was 12.3 per 1,000 live births; with the expansion of the available databases this figure has risen to 12.6 per 1,000 live births. Mortality rates have been age-adjusted where necessary; the death data were as presented by the countries, with no corrections for underreporting of deaths.

### Findings

The values of the projections for the six health indicators for 2014 and 2019, the expected values for 2019, and the estimated percentage change with their respective CI, are shown in table.

TABLE

► Regional goals, projected health indicators, and percentage change between 2014 and 2019

Indicator	Goal	2014 Projection	2019 Expected Value*	2019 Projection	Percentage increase/reduction (CI 95%)	Remarks based on CI
Healthy life expectancy at birth	At least 1% increase in healthy life expectancy at birth	66.7	67.4	67.9	1.8% (CI: [1.2%; 2.3%])	The goal will be reached and probably surpassed
Infant mortality rate	At least 15% reduction in infant mortality rate	12.6	10.7	11.1	-12.1% (CI: [-21.6%; -2.7%])	The goal will be reached
Maternal mortality ratio	At least 11% reduction in maternal mortality ratio	53.3	47.4	47.5	-10.9% (CI: [-16.5%; -5.2%])	The goal will be reached
Mortality due to poor quality of health care	At least 9% reduction in mortality due to poor quality of health care	118.6	107.9	108.1	-8.9% (CI: [-12.1%; -6.0%])	The goal will be reached
Premature deaths due to noncommunicable diseases	At least 9% reduction in premature deaths due to noncommunicable diseases	262.7	239.1	242.9	-7.6% (CI: [-8.0%; -7.1%])	There is no statistical evidence to conclude that the goal will be reached, but the estimate indicates that the trend is moving in the direction of reaching the goal.
HIV/AIDS mortality	At least 15% reduction in HIV/AIDS mortality	3.8	3.2	3.2	-16.3% (CI: [-20.2%; -13.1%])	The goal will be reached and probably surpassed.

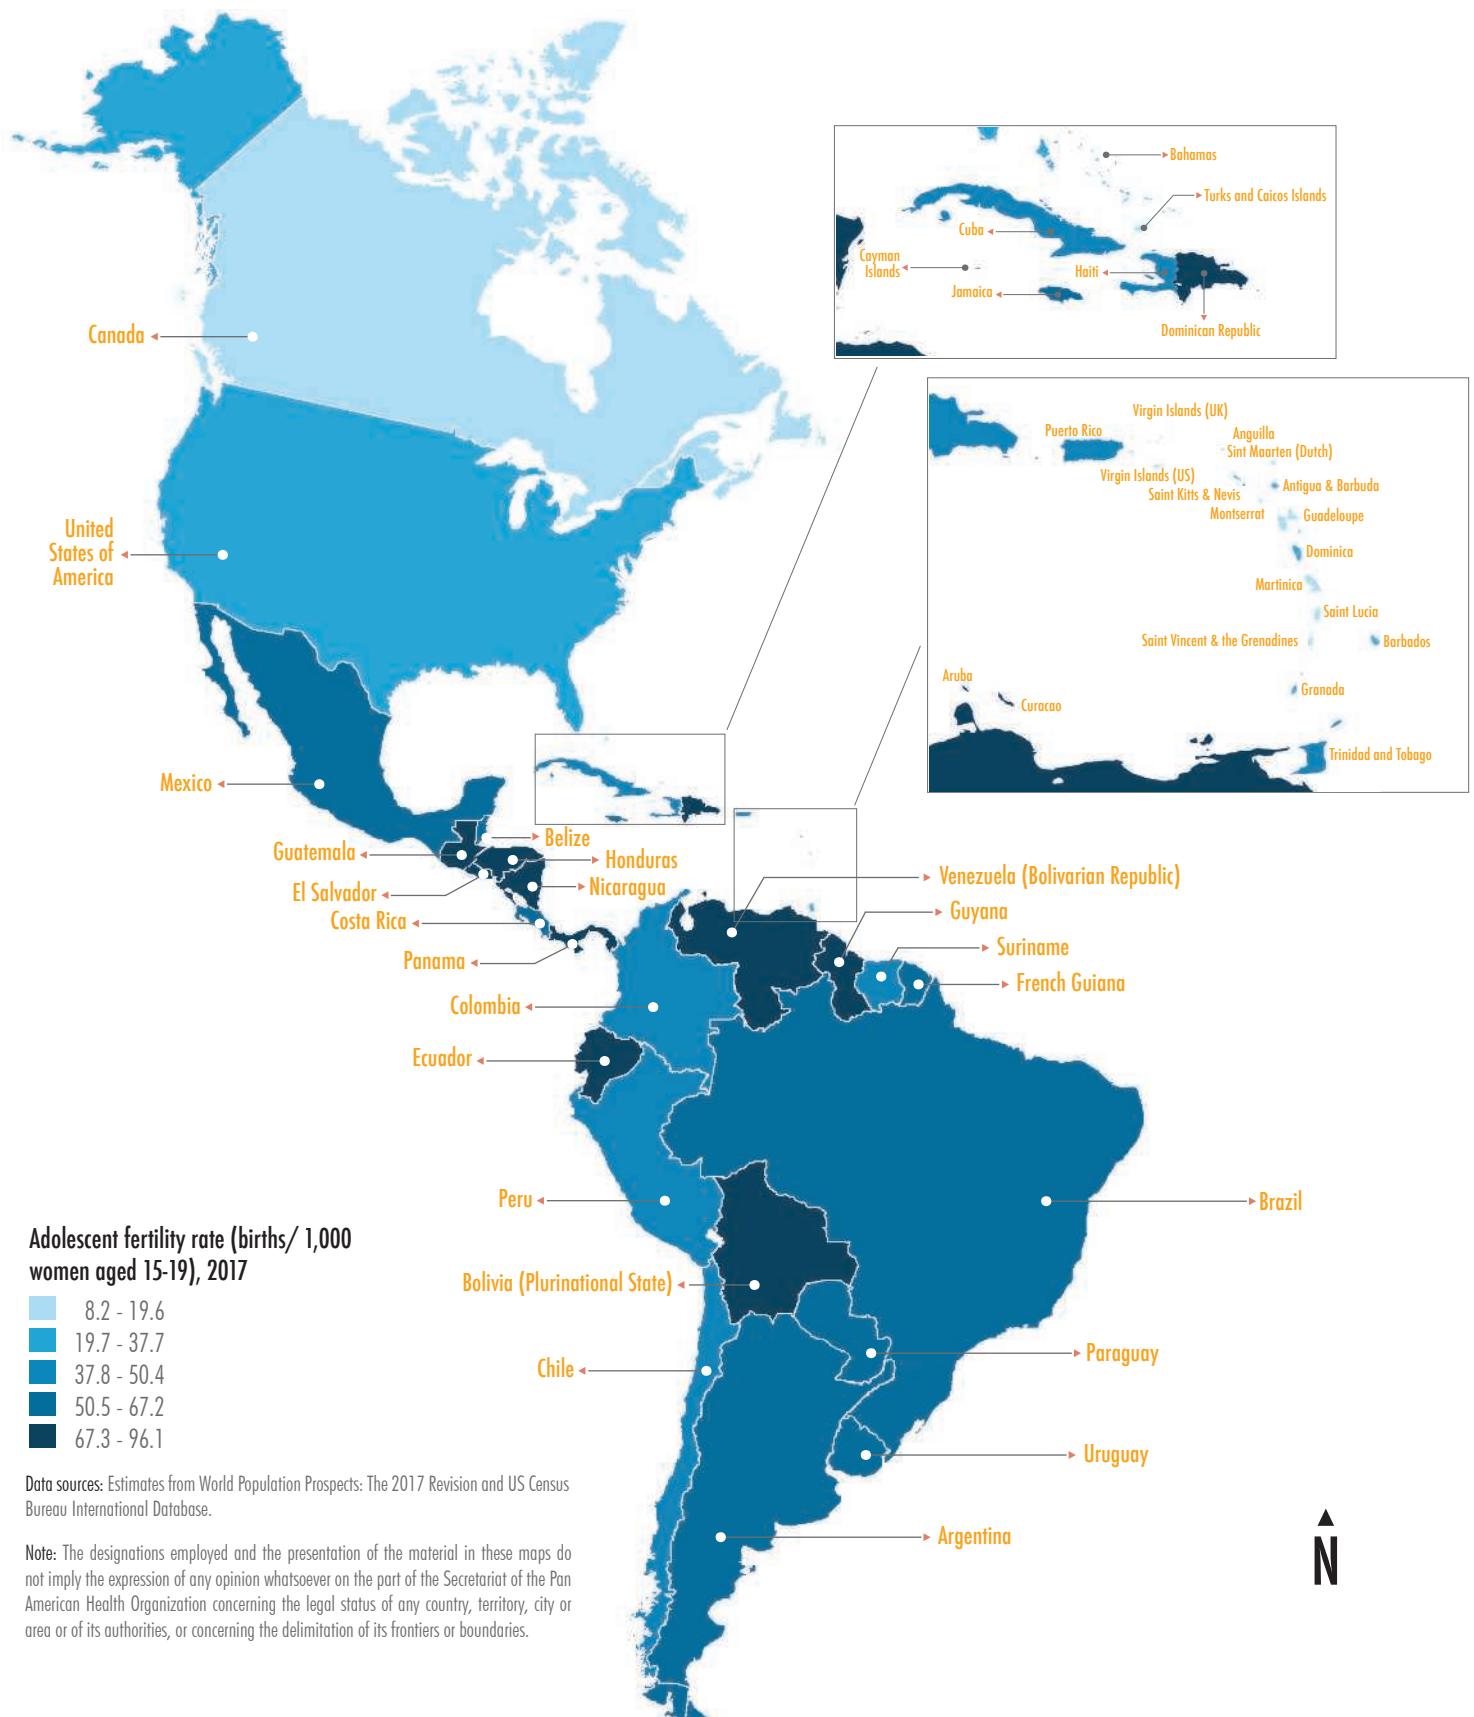

Note: (\*) Value of the indicator after applying the percentage of expected increase or reduction.

It is assumed that if countries continue to act at their current pace, the trend of the indicators will follow the trajectory presented here. These findings suggest that health authorities in the Region's countries should work to reinforce prevention and control activities with respect to each of the goals in order to safeguard the progress already achieved, or, alternatively, work to improve their strategies in order to increase the probability that the 2019 targets will be met.

## FERTILITY IN ADOLESCENTS

Adolescent pregnancy is one of the main factors contributing to maternal and infant mortality, and has negative social and economic repercussions for adolescents, their families and their communities. Many pregnant teenagers are forced to drop out of school; they furthermore have fewer opportunities to find employment when they do not complete their education. The Region has the second highest adolescent fertility rate in the world; the map shows the adolescent fertility rate in the 15 to 19 year age group for 2017. The highest rate corresponds to the Dominican Republic, with 96.1 per 1,000 women aged 15-19, followed by Nicaragua (86.9) and Guyana (86.7). The country with the lowest rate was Montserrat (8.2), followed by the US Virgin Islands (9.4) and Canada (9.8). It is important to promote and protect adolescent sexual and reproductive health to ensure optimal access to information, education, and access to appropriate health services, including access to contraceptives.

## ▷ DEFINITIONS

### ► Median age (BI 2)

Divides the population in two parts of equal size, that is, there are as many persons with ages above the median as there are with ages below the median.

### ► Mean years of schooling (BI 12)

Is the average number of completed years of education of a country's population aged 25 years and older, excluding years spent repeating individual grades.

### ► Gini Index (BI 16)

Measures income inequality. The Gini is zero if everyone had the same income and is 100 if a single person had all the income.

### ► Maternal mortality ratio (BI 17), infant mortality rate (BI 20), neonatal mortality rate (BI 22) and under-5-mortality (BI 23)

Country reported data to PAHO from vital registration, survey, special studies, or national estimates. An increase may reflect an improvement in data coverage and quality.

- **Maternal mortality ratio** as reported by the countries (Ecuador, El Salvador, Guatemala, Guyana, Nicaragua, Panama, Paraguay, Peru) presents limitations of one or more of the following: coverage of maternal deaths and live births, differences in the maternal death definition, different denominators used or the analysis of only confirmed maternal deaths.
- **Infant and neonatal mortality rates** as reported by the countries (Ecuador, El Salvador, Guatemala, Panama, Paraguay, Peru, Suriname) present limitations due to the coverage of infant and neonatal deaths or the number of live births.

### ► Dengue cases (BI 27)

The number of suspected and laboratory confirmed cases from dengue and severe dengue. *Country data*.

### ► Leprosy cases (BI 31)

Cases registered for treatment on 31 December of a given year. *Country data*.

### ► Mortality indicators (BI 35-48)

Presented according to the Global Burden of Disease list study: communicable diseases, non-communicable diseases, and external causes as well as specific selected causes.

- All rates are age-adjusted death rates with the WHO World Standard Population. (<http://www.who.int/healthinfo/paper31.pdf>)
- Corrected mortality rates are computed based on registered mortality data, applying a correction algorithm for mortality under-registration and a redistribution algorithm for deaths from ill-defined causes and events of undermined intent as presented in Health Statistics from the Americas, 2006 edition (<http://www.paho.org/HSA2006>).
- Rates are presented for the years 2013, 2014 or 2015. Data was excluded when the latest mortality rates were already shown twice: Cayman Islands (2014) and Honduras (2013). Country data not included from: Bolivia (2003), Curacao (2007), Haiti (2004), Jamaica (2011), Trinidad and Tobago (2010), UK Virgin Islands (2010). Data not available for Sint Maarten (Dutch).

### ► Stunting in children (BI 51)

Defined as children aged 0-5 years and height-for-age less than -2 standard deviations of the WHO Child Growth Standards median. *Country data*.

### ► Overweight in children (BI 52)

Defined as children aged 0-5 years with overweight of over two standard deviations from the median weight-for-height of the WHO Child Growth Standards. *Country data*.

### ► Overweight and obesity in adults (BI 53)

Refers to persons aged 18 and over with overweight and obesity defined as a body mass index (BMI)  $\geq 25.0 \text{ kg/m}^2$ , age-standardized. Updated estimations for this indicator were performed by WHO for 2014. These estimates are based on models adjusted when amendments/corrections exist for data. *WHO estimates*.

### ► Insufficient physical activity (BI 54)

Refers to adults aged 18 and over that attain less than 150 minutes of moderate-intensity physical activity per week, age-standardized. *WHO estimates*.

### ► Prevalence of current tobacco use in adolescents (BI 55)

Refers to persons aged 13-15 which have used at least once any tobacco product, smoked or smokeless, during the 30 days prior to the survey. *Country data*.

### ► Prevalence of current tobacco smoking in adults (BI 56)

Refers to persons aged 15 and over that smoked any tobacco product during the 30 days prior to the survey, age-standardized. This includes daily and occasional smoker. *WHO estimates*.

### ► Alcohol consumption (BI 57)

Refers to the total amount (recorded plus estimated unrecorded) of pure alcohol (ethanol) consumption per person (liter/per capita) aged 15 years and older, within a calendar year. *WHO estimates*.

### ► Prevalence of raised systolic blood pressure (BI 58)

Refers to persons aged 18 and over with raised blood pressure defined as systolic blood pressure  $\geq 140 \text{ mm Hg}$  or diastolic blood pressure  $\geq 90 \text{ mm Hg}$ , age-standardized. *WHO estimates*.

### ► Prevalence of raised fasting blood glucose/diabetes (BI 59)

Refers to persons aged 18 and over with fasting glucose  $\geq 126 \text{ mg/dl}$  (7.0 mmol/l) or on medication for raised blood glucose, age-standardized. *WHO estimates*.

### ► Population that depends mainly on solid fuels and/or kerosene (BI 62)

Refers to the proportion of households that depends mainly on solid fuels and/or kerosene for cooking. *WHO estimates*.

### ► Contraceptive prevalence, modern methods (BI 70)

Refers to women aged 15 to 49 years, married or in union, who are currently using (or whose sexual partner) one modern method of contraception. Modern contraceptive methods include female and male sterilization, injectable and oral hormonal pills, intrauterine devices, implant (including Norplant), vaginal barrier methods, diaphragm, the female condom and emergency contraception. *UN Estimates*.

### ► Unmet need for family planning: women (BI 71)

Refers to women who are fecund and sexually active but are not using any modern method of contraception, and report not wanting any more children or wanting to delay the next child, expressed as percentage of fecund women who are married or in an union. *UN Estimates*.

### ► Public and private health expenditure as % of GDP (BI 77)

- **Public expenditure** is the sum of health outlays paid for in cash or supplied in kind by general government entities, at the central, regional and local level and social security agencies (avoiding double counting government transfers to social security and extra budgetary funds). It includes transfer payments to households (mainly the reimbursement of health services and medicines expenses) and extrabudgetary funds to finance health services and goods. Revenues can come from multiple domestic sources and external funds
- **Private expenditure** is the sum of outlays for health by private entities, such as commercial or mutual health insurance, non-profit institutions serving households, resident corporations and quasi-corporations that provide or finance health services and household direct or out-of-pocket expenditures. *WHO Estimates*.

### ► Out-of-pocket expenditure as % of THE (BI 78)

Includes payments made by an individual or households at the point of service regardless if the service is provided in a formal setting (clinic, hospital, pharmacy) or informal setting (complementary medicine) - and always deducting any refund. *WHO Estimates*.

### ► Mortality garbage codes (BI 82)

Proportion of deaths that were assigned to causes that are not considered useful for public health purposes; Naghavi et al (2010): Algorithms for enhancing public health utility of national causes-of-death data and were adapted by PAHO/CRAES. *WHO/PAHO calculations based on country data*.

## ► NOTES

- Data presented is the latest available information at PAHO/WHO as of May 2017.
- In this edition, the most recent available year is presented; the lower year limit is 2007.
- Rates are calculated based on population data from World Population Prospects (WPP) and the US Census Bureau International databases.
- International agencies are continuously revising and improving their methodologies which can result in differences to previously reported data.
- Data was reviewed for completeness, consistency, and comparability but users should interpret data with caution as definitions and data accuracy can differ among countries.
- Rates of the following countries should be viewed with caution due to small number of events: Anguilla, Antigua and Barbuda, Aruba, Barbados, Bermuda, Cayman Islands, Curacao, Dominica, Grenada, Montserrat, Saint Kitts and Nevis, Saint Vincent and the Grenadines, Sint Maarten (Dutch), Saint Lucia, Turks and Caicos Islands, UK and US Virgin Islands.
- We continue to collect core indicators from Bonaire, San Eustatius and Saba (BES). In this edition, BES is not included yet.
- The regional and subregional aggregates for rates, ratios and proportions are weighted averages, and sums for absolute numbers. Subregionals figures are only shown when data is available for at least 50% of the population within the subregion.
